1.

An engineer investigates the use of a light dependent resistor (LDR) as a light sensor in a potential divider circuit. He designs the following sensing circuit to operate a 230 V lamp in the dark.

The control circuit draws a negligible current. During his research, the engineer determines the following facts:

The control circuit requires at least 4.0 V to activate. The LDR the engineer intends to use has a resistance of 2.4 k Ω at the light intensity required to switch the lamp on.

Explain how the current in the LDR changes as the light intensity decreases.

[2]

(ii)	Determine a suitable value for the fixed resistor R , which would allow the lamp to be switched on. [3]
(b)	When installing the circuit, the engineer made the mistake of placing the lamp near to the LDR. The engineer noted that, when in the dark, the lamp kept turning on and of repeatedly rather than staying on. Explain why this was the case.

2	(a)	(i)	State what is meant by electric current.	[1]

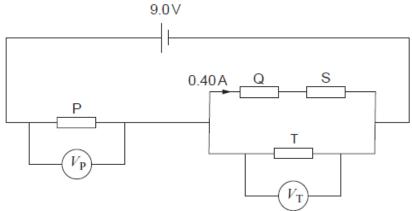

Show that the unit of resistance, the ohm (Ω) , can be expressed as:

(ii)

Js C⁻²

[2]

(b) The following circuit shows an arrangement of **identical resistors** labelled P, Q, S and T connected to a fixed pd of 9.0 V. $V_{\rm P}$ and $V_{\rm T}$ are the pds across P and T respectively. There is a current of 0.40 A in Q and S.

(i)	Show that $V_{\rm P}$ = 1.5 $V_{\rm T}$.	[2]
(ii)	Hence or otherwise show that the values given in the diagram are consist the resistance of each resistor being 4.5 Ω .	tent with [3]

(c)	Show that the total energy dissipated per second in the whole circuit is 15 times more than the energy dissipated per second in resistor Q. [3]	
(d)	Resistor T is now removed from the circuit. Explain the effect this will have on the ratio calculated in part (c). [3]	

(i)

(ii)

Calculate the pd across A and B.

(a) Define the capacitance of a capacitor.	[1]
(b) Two capacitors, initially uncharged, are arranged in series as shown. When a batte connected across A and B, the charge on plate P is found to be +75 nC.	ery is
A 10 nF 30 nF B P Q R S	
Write down the charges on each of the plates Q, R and S. Give a reason for your answer to the charge on plate S. [3]	
Charge on Q:	
Charge on R:	
Charge on S:	
Reason:	

[2]

(iii)	A Physics student makes the following comment:
	For capacitors in series, a capacitor of higher capacitance stores more energy than a capacitor of smaller capacitance.
	By considering this combination of capacitors, investigate whether or not the student is correct. [2]
(c)	Some computer keyboards work on the principle of varying capacitance. When a key is pressed, a spring is compressed and the separation of two parallel metal plates is decreased. The computer responds if the increase in capacitance of the plates is 0.20 pF or more. The diagram shows how a single key is constructed.
Мо	Fixed keyboard base veable metal plate Fixed metal plate Initial separation of plates = 5.2×10^{-3} m Initial capacitance = 0.27 pF Plate area = 1.6×10^{-4} m ²
	The designers of a keyboard require that the increase in capacitance of 0.20 pF occurs when a force of 0.20 N is exerted on a key. Different springs are available, of spring constant $90\mathrm{Nm^{-1}}$, $120\mathrm{Nm^{-1}}$ and $150\mathrm{Nm^{-1}}$. Determine which (if any) of these springs would be suitable in meeting the designer's requirements. The capacitor is filled with air. [4]
