## Immune response

Physical barriers to infection include:

- Skin is a tough physical barrier consisting of keratin
- Stomach Acid (hydrochloric acid) which kills bacteria
- Gut and skin flora natural bacterial flora competes with pathogens for food and space

Non-specific responses of the body to infection include:

- Inflammation histamines released by damaged white vessels cause vasodilation which increases the flow of blood to the infected area and increases permeability of blood vessels. As a result of that antibodies, white blood cells and plasma leak out into the infected tissue and destroy the pathogen
- Lysozyme action lysozyme is an enzyme found in secretions such as tears and mucus which kills bacterial cells by damaging their cell wall
- Interferon interferons prevent viruses spreading to uninfected cells by stopping protein synthesis in viruses
- **Phagocytosis** is a process in which white blood cells engulf pathogens thus destroying them by fusing a pathogen such as bacteria enclosed in a phagocytic vacuole with a lysosome.

After the pathogen is engulfed and destroyed, its chemical markers called **antigens** are then **presented on the surface of the phagocyte**. The phagocyte then becomes an **antigen presenting cell** which actives other types of immune system, immune response will be stimulated if the antigen is recognised as foreign.

The specific immune response is antigen specific and produces responses specific to one type of pathogen only. This type of immune response relies on lymphocytes produced in the bone marrow:

- B cells mature in the bone marrow and are involved in the humoral response
- **T cells** move from the bone marrow to the thymus gland where they mature, they are involved in **cell mediated response**

## Specific immune response glossary:

 Memory cells are cells which replicate themselves when exposed to an invading pathogen and remain in the lymph nodes searching for the same antigen thus resulting in a much faster immune response

## Immunity

Immunity can either be active or passive; active immunity results from the production of antibodies by the immune system in response to the presence of an antigen whereas passive immunity results from the introduction of antibodies from another person or animal. There are also two subtypes of immunity; natural or artificial:

- Natural active immunity arises from being exposed to an antigen/getting the disease whereas natural passive immunity is the result of crossing of mother's antibodies through the placenta and their presence in breast milk.
- Active artificial immunity is acquired through vaccinations which stimulate the immune system and lead to production of antibodies whereas passive artificial immunity is where antibodies are injected into the body.
