### ADDITIONAL MATERIALS

In addition to this paper you may require a calculator and a ruler.

### **INSTRUCTIONS TO CANDIDATES**

Use black ink or black ball-point pen. Do not use gel pen or correction fluid.

You may use a pencil for graphs and diagrams only.

Write your name, centre number and candidate number in the spaces at the top of this page. Answer **all** questions.

Write your answers in the spaces provided in this booklet. If you run out of space, use the additional page(s) at the back of the booklet, taking care to number the question(s) correctly.

### **INFORMATION FOR CANDIDATES**

The number of marks is given in brackets at the end of each question or part-question. The assessment of the quality of extended response (QER) will take place in question **8**. The quality of written communication will affect the awarding of marks.

<image>

A labelled branch on Image 1.1 represents a group called the cyanobacteria. Image 1.2

mémbranes containing photosynthetic pigments

Some bacteria contain an enzyme called nitrogenase. This enzyme is used in nitrogen fixation. It does not function in the presence of oxygen.

(i) Describe and explain the evidence from **Image 1.2** that shows that nitrogen fixation is not taking place in this cyanobacterium.

 Scientists used to classify cyanobacteria in the Kingdom Protoctista. With reference to their cell structure, suggest why they have been reclassified as bacteria.

[2]

2. Scientists studied the changes associated with growth occurring in the root tip region of wheat plants. They measured the dry mass of cells and the volume of cells at different distances from the root tip.

The results are shown in **Table 2.1**.

### Table 2.1

| Distance from end of root tip<br>/mm | Mean dry mass of cells<br>/pg | Mean volume of cells<br>/µm <sup>3</sup> |
|--------------------------------------|-------------------------------|--|

| 2                                    | 2.5                           | 25                                       |
| 3                                    | 2.5                           | 35                                       |
| 4                                    | 3.5                           | 45                                       |
| 5                                    | 4.5                           | 55                                       |
| 6                                    | 5.5                           | 65                                       |

(a) Suggest why there is an increase in the volume of the cells between 1 and 3 mm from the end of the root tip, even though the dry mass remains constant. [2]

(b) A student made a root tip squash to observe mitosis. They used hydrochloric acid to separate the cells by breaking down the chemicals which bind cells together.

The instructions they followed then stated:

'Make sure that the slide is on a flat surface and squash down on the coverslip with a strong vertical pressure using your thumb. Do not twist or roll the thumb from side to side.'

(i) Explain why the student is told to 'squash down with strong vertical pressure' **and** not to 'twist or roll the thumb from side to side'. [2]

(e) A group of scientists used golden hamsters (*Mesocricetus auratus*) to study the acrosome reaction.

Two groups of male hamsters were used.

Group 1: produced normal sperm.

Group 2: genetically modified to produce sperm that did not carry out acrosin production.

Two sets of ova were then taken from female hamsters. These were treated in two different ways.

Set A: Ova were left complete.

Set B: The zona pellucida were removed from around the ova.

The sperm from both groups were then mixed with the ova from each set in vitro.

The percentage of the oocytes that were fertilised was calculated and the results are shown in **Table 4.4**.

## Table 4.4

| Sperm and ova types   | % of oocytes<br>fertilised |
|---|----------------------------|
| Group 1 (normal) sperm with Set A (normal) ova                | 89                         |
| Group 1 (normal) sperm with Set B (no zona pellucida) ova     | 100                        |
| Group 2 (no acrosin) sperm with Set A (normal) ova            | 0                          |
| Group 2 (no acrosin) sperm with Set B (no zona pellucida) ova | 100                        |

(i) Use the information given in **Table 4.4** to suggest what conclusions could be made about the role of acrosin. Explain your answer.

# PLEASE DO NOT WRITE ON THIS PAGE

5. Cas9 is a DNA endonuclease that is associated with a strand of guide RNA (gRNA). The enzyme unwinds DNA and breaks the hydrogen bonds between the DNA strands. The base sequence on part of the gRNA then aligns next to a specific target sequence on the DNA. The endonuclease then makes a double stranded cut at this target sequence. During the repair of the DNA molecule a double-stranded length of DNA can be inserted. This is shown in **Image 5**.

14

7. Scientists studied the diet and length of jaws of tiger snakes (*Notechi scutatus*) on the mainland of Australia and an island 5 km off its coast.

When captured and handled, some of the snakes regurgitated their prey. This allowed the scientists to identify the diet of the snakes. The results are shown in **Table 7.1**.

## Table 7.1

| Area snake found    | Prey               | Mass of prey/g | Circumference<br>of prey/mm | Number of<br>snakes in which<br>prey item found |
|---------------------|--------------------|----------------|-----------------------------|---|
| Island              | Seagull chick      | 133.10         | 155.00                      | 1   |
| Island              | Silver gull chick  | 39.70          | 121.80                      | 10  |

The scientists wanted to investigate the effect of prey size on jaw development in snakes.

- They used newly hatched snakes from both locations; 123 snakes were measured from the island and 129 from the mainland.
- The snakes were fed either large or small mice over several months until they reached maturity.
- The jaw length of each snake was measured from the tip of the nose to the point of articulation of the upper jaw using digital callipers with a precision of 0.01 mm.

The results are shown in Table 7.2.

#### Table 7.2
