

Endothermic reaction

Reaction profiles show energy changes

Exothermic reaction

Activation energy

Reaction profiles

Chemical reactions take place when the reacting particles collide with sufficient energy

Explain in terms of endothermic and exothermic reactions

The energy needed to break existing bonds is greater than the energy released from forming new bonds

The energy released from forming new bonds is greater than the energy needed to break existing bonds

Energy change of reactions

5.1 EXOTHERMIC AND ENDOTHERMIC REACTIONS

Energy transfer

Conservation of energy

Overall amount of energy does not change

Thermal decomposition

Citric acid and sodium hydrogencarbonate

Examples

Everyday uses

Sports injury packs

Endothermic reaction

Energy is taken in from the surroundings

Temperature of the surroundings decreases

Exothermic reaction

Energy is transferred to the surroundings

Temperature of the surroundings increases

Examples

Many oxidation reactions

Combustion

Neutralisation

Everyday uses

Hand warmers

During a reaction...

Energy must be supplied to break reactant bonds

Energy is released when products' bonds are formed

Overall energy change is the difference between the sum of the energy needed to break reactant bonds and the sum of the energy released when products' bonds are formed

KEY

'Higher only' written in yellow.
