

**AQA Computer Science A-Level**  
**4.3.4 Searching algorithms**  
Concise Notes

## **Specification:**

### **4.3.4.1 Linear search:**

Know and be able to trace and analyse the complexity of the linear search algorithm. Time complexity is  $O(n)$ .

### **4.3.4.2 Binary search**

Know and be able to trace and analyse the time complexity of the binary search algorithm. Time complexity is  $O(\log n)$ .

### **4.3.4.3 Binary tree search**

Be able to trace and analyse the time complexity of the binary tree search algorithm. Time complexity is  $O(\log n)$ .

## Searching Algorithms

- A **searching algorithm** is used to find a **specified data item** within a **set of data**

### Linear Search

- Can be conducted on **any list**, even if the data isn't in order
- Works by inspecting every item in a list **one by one** until the desired item is found
- **Very simple** to program
- Comparatively **high time complexity** of  $O(N)$
- If the target **does not exist** in the list, the algorithm will still **check every single item** in the list

### Binary Search

- Can only be used on **ordered** lists
- Works by looking at the **midpoint** of a list and determining if the **target** is **higher or lower** than the midpoint
- More efficient than the linear search algorithm
- Midpoint calculated by **adding the first and last positions** of the data, and **dividing by two**
- The list of data is **halved** with each iteration
- Can be implemented both **iteratively** and **recursively**
- Good time complexity of  $O(\log N)$

### Binary Tree Search

- The same as a binary search, but conducted on a **binary tree**
- A binary tree is a **rooted, ordered tree** in which **each node has no more than 2 children**
- Can be implemented both **iteratively** and **recursively**
- Same time complexity as binary search,  $O(\log N)$
