## Communication basics

Before understanding different methods of communication, it helps to understand some **key concepts** in communication.

### Symbol

A symbol is a **particular pattern of bits** represented by a signal. For example, a symbol of four bits might be 1101.

### Baud rate

A communication system's Baud rate is the **number of signal changes** in the medium **per second**. 1 Baud (or 1Bd) is equal to 1 symbol change per second.

### Bit rate

A communication medium's bit rate refers to the **number of bits that are transmitted** over the medium **per second**. This is often measured in **bits per second** (bps).

Therefore, a communication system's bit rate is equal to its Baud rate **multiplied by the number of bits per signal** in the communication medium.

$$\text{Bit rate} = \text{Baud rate} \times \text{No of bits per signal}$$

A communication medium's **bit rate** will be **higher than its Baud rate** if there is **more than one bit** sent per signal.

### Bandwidth

Bandwidth, expressed in **Hertz**, relates to the **range of frequencies** that a communication medium is capable of transmitting. There is a **direct relationship** between bandwidth and bit rate. Higher bandwidth results in a **higher bit rate**.

### Latency

Latency in a communication medium, often measured in **milliseconds**, is the **difference in time between an action being initiated and its effect being noticed**. For example, if you press the "R" key on your keyboard and the letter R appears on screen 26ms later, the latency in the link between your keyboard and the application you are using is 26ms. Latency usually **increases** with distance.

### Protocol

A protocol is a **set of rules** relating to communication between devices. International organisations decide upon and publish protocols which allow devices made by **different manufacturers** in **opposite ends of the world** to communicate seamlessly.

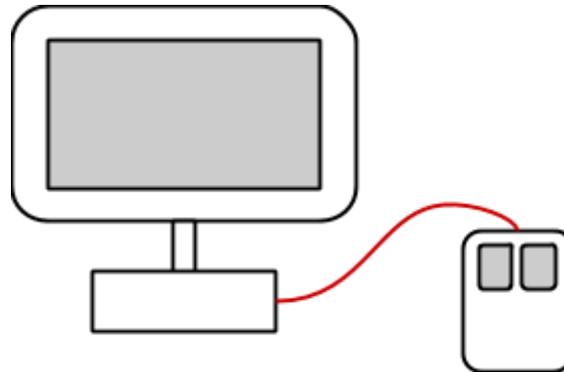

## Serial and parallel data transmission

Computers can transmit data between their different components in two ways: serially or in parallel.

### Serial data transmission

In serial data transmission, data is sent **one bit at a time** over one communication line (this is usually a **metal wire**, but could also be an **optical fibre** or a **wireless channel**).

Serial data transmission is frequently used for transmitting data over **medium to long distances** (computationally speaking), such as from wired peripherals like **mice** and **keyboards** to your computer.

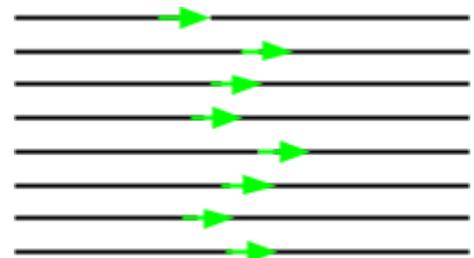

### Parallel data transmission

Parallel data transmission uses **numerous parallel communication lines** in order to send **multiple bits** between components in a computer **simultaneously**.

The more lines that a parallel communication medium uses, the more data can be transferred simultaneously.

Each of the communication lines that forms part of a parallel communication medium will have **slightly different electrical properties**, meaning that the time taken for one bit to be transferred will **differ slightly** from line to line. This means that bits sent together may not be received together, a problem referred to as **skew**.

Skew is worst over long distances and, in extreme cases, can lead to bits from different pulses **overlapping**, causing **corruption** of data. Furthermore, parallel communication mediums are **more expensive** than their serial counterparts because of their use of multiple lines. For these reasons, parallel data transmission is most often used **over short distances**, such as **between parts of the processor** and **within RAM**.

Another issue, referred to as **crosstalk**, can occur with parallel data transmission. When communication lines are **tightly packed**, signals from one line can “leak” into another, another cause of **data corruption**.

### The advantages of serial over parallel

Serial data transmission **doesn't suffer from skew or crosstalk** making it a **more reliable communication method**, especially over **long distances**. Serial communication mediums, which use **just one line**, are **cheaper** to install than parallel mediums which use more than one line.

## Synchronous and asynchronous data transmission

### Synchronous transmission

When data is transmitted using synchronous transmission, a **clock signal** (which is shared by both the sender and the receiver) is used to time when signals are sent. Synchronous data transmission is used within the busses of a computer's processor in the **fetch-execute cycle**.

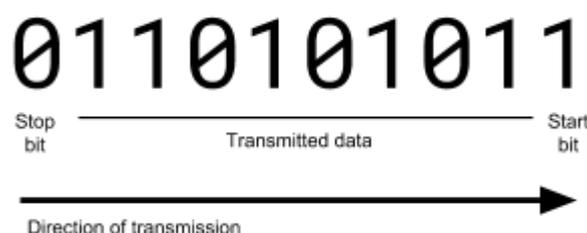

### Synoptic Link

The **fetch-execute cycle** is covered in detail in the notes for **structure and role of the processor and its components** under **fundamentals of computer organisation and architecture**.

The signals, which are sent at **regular intervals**, will be received **in the same order** that they were sent. This makes synchronous data transmission suitable for transmitting information in **real-time systems**.

### Asynchronous transmission

In asynchronous data transmission, the requirement for a shared clock signal **is done away with** by using **start and stop bits** to indicate the **duration of a transmission**.

The start bit can be **either a 0 or a 1** and the stop bit is **always the opposite** of the start bit.

The sender and receiver must use **the same Baud rate** and need only synchronise their clocks **for the duration of data transmission**.
