

C1 January 2012 (MA)

Q1)  $y = x^4 + 6x^{\frac{1}{2}}$

a)  $\frac{dy}{dx} = 4x^3 + 3x^{-\frac{1}{2}}$   
 $= \boxed{4x^3 + \frac{3}{\sqrt{x}}}$

b)  $\int (x^4 + 6x^{\frac{1}{2}}) dx = \frac{x^5}{5} + \frac{6x^{\frac{3}{2}}}{\frac{3}{2}} + C$   
 $= \frac{x^5}{5} + 4x^{\frac{3}{2}} + C$

$= \boxed{\frac{x^5}{5} + 4x\sqrt{x} + C}$

Q2a)  $\sqrt{32} + \sqrt{18} = \sqrt{8}\sqrt{4} + \sqrt{9}\sqrt{2}$   
 $= \sqrt{2}\sqrt{4}\sqrt{4} + \sqrt{9}\sqrt{2}$   
 $= 4\sqrt{2} + 3\sqrt{2}$   
 $= \boxed{7\sqrt{2}}$

b)  $\frac{\sqrt{32} + \sqrt{18}}{3 + \sqrt{2}} = \frac{\sqrt{32} + \sqrt{18}}{3 + \sqrt{2}} \times \frac{3 - \sqrt{2}}{3 - \sqrt{2}}$   
 $= \frac{(\sqrt{32} + \sqrt{18})(3 - \sqrt{2})}{(3 + \sqrt{2})(3 - \sqrt{2})}$   
 $= \frac{7\sqrt{2}(3 - \sqrt{2})}{(3 + \sqrt{2})(3 - \sqrt{2})}$

$$= \frac{21\sqrt{2} - 14}{9 - 3\sqrt{2} + 3\sqrt{2} - 2}$$

$$= \frac{21\sqrt{2} - 14}{7}$$

$$= 3\sqrt{2} - 2$$

Q3a)  $4x - 5 > 15 - x$

$$5x > 20$$

$$x > 4$$

b)  $x(x - 4) > 12$

$$x^2 - 4x > 12$$

$$x^2 - 4x - 12 > 0$$

For  $x^2 - 4x - 12 = 0$

$$(x - 6)(x + 2) = 0$$

Either  $x = 6$  or  $x = -2$

Set of possible values for  $x$ :

$$x < -2 \text{ or } x > 6$$

Q4)  $x_1 = 1$   
 $x_{n+1} = ax_n + 5, \quad n \geq 1$

a)  $x_2 = ax_1 + 5$

$$x_2 = a(1) + 5$$

$$\boxed{x_2 = a + 5}$$

b)  $x_3 = ax_2 + 5$

$$x_3 = a(a + 5) + 5$$

$$\boxed{x_3 = a^2 + 5a + 5}$$

c) If  $x_3 = 41$ ,  $a^2 + 5a + 5 = 41$

$$a^2 + 5a - 36 = 0$$

$$(a + 9)(a - 4) = 0$$

$$\boxed{\text{Either } a = -9 \text{ or } a = 4}$$

Q5) curve C:  $y = x(5 - x)$ . curve L:  $2y = 5x + 4$

$$\begin{array}{l|l|l} y = 5x - x^2 & \textcircled{1} & x^2 \\ 2y = 5x + 4 & \textcircled{2} & x^1 \end{array} \quad \begin{array}{l} 2y = 10x - 2x^2 \\ 2y = 5x + 4 \end{array}$$

Substitute  $\textcircled{1}$  into  $\textcircled{2}$ :

$$10x - 2x^2 = 5x + 4$$

$$2x^2 - 5x + 4 = 0$$

$$\begin{aligned}
 b^2 - 4ac &\equiv (-5)^2 - (4)(2)(4) \\
 &= 25 - 32 \\
 &= \underline{-7}
 \end{aligned}$$

Since  $b^2 - 4ac < 0$ , there are no real solutions for the equation  $C=L$  and thus the curves do not intersect.

b) curve c:  $y = x(5-x)$

When  $x=0$ ,  $y = 0(5-0) = \underline{0}$

When  $y=0$ ,  $x(5-x)=0$   
Either  $x=0$  or  $x=5$

Line L:  $2y = 5x + 4$

When  $x=0$ ,  $2y=4 \Rightarrow \underline{y=2}$

When  $y=0$ ,  $0=5x+4 \Rightarrow \underline{x = -\frac{4}{5}}$

Q6a)  $2x - 3y + 12 = 0$

$$3y = 2x + 12$$

$$y = \frac{2}{3}x + 4$$

|                                 |
|---------------------------------|
| $\text{Gradient} = \frac{2}{3}$ |
|---------------------------------|

b) When  $2x - 3y + 12 = 0$  cuts the y-axis,  $x = 0$

$$\therefore -3y + 12 = 0$$

$$3y = 12$$

$$y = 4$$

$\therefore B$  is at  $(0, 4)$

A perpendicular line would have a gradient of  $\underline{-\frac{3}{2}}$ ,

(since  $\frac{2}{3} \times -\frac{3}{2} = -1$ )

Since the perpendicular line passes through B, use  $x$ , as 0 and  $y$ , as 4, and  $m$  as  $-\frac{3}{2}$ :

Equation of perpendicular line:

$$y - y_1 = m(x - x_1)$$

$$y - 4 = -\frac{3}{2}(x - 0)$$

$$2(y - 4) = -3(x - 0)$$

$$2y - 8 = -3x$$

$$\boxed{2y + 3x - 8 = 0}$$

c) When  $2x - 3y + 12 = 0$  cuts the  $x$ -axis,  $y = 0$

$$\therefore 2x + 12 = 0$$

$$x = -6$$

$\therefore A$  is at  $(-6, 0)$

When  $2y + 3x - 8 = 0$  crosses the  $x$ -axis,  $y = 0$

$$\therefore 3x - 8 = 0$$

$$3x = 8$$

$$x = \frac{8}{3}$$

$\therefore C$  is at  $(\frac{8}{3}, 0)$

$$\begin{aligned}
 \text{Area } \triangle ABC &= \frac{1}{2} bh = \frac{1}{2} (AC)(OB) \\
 &= \frac{1}{2} \left( \frac{26}{3} \right) (4) \\
 &= \frac{1}{2} \left( \frac{104}{3} \right) \\
 &= \boxed{\frac{52}{3} \text{ units}^2}
 \end{aligned}$$

Q7)  $f'(x) = 3x^2 - 3x + 5$

$$f(x) = \int (3x^2 - 3x + 5) dx$$

$$f(x) = x^3 - \frac{3x^2}{2} + 5x + C$$

---

Since  $f(x)$  passes through  $(2, 10)$ ,  
substitute in  $x=2$  and  $f(x)=10$ :

$$10 = 2^3 - \frac{3(2)^2}{2} + 5(2) + C$$

$$10 = 8 - 6 + 10 + C$$

$$10 = 12 + C$$

$$\therefore \underline{C = -2}$$

$$f(x) = x^3 - \frac{3x^2}{2} + 5x - 2$$

$$f(1) = 1^3 - \frac{3(1)^2}{2} + 5(1) - 2$$

$$= 1 - \frac{3}{2} + 5 - 2$$

$$= 4 - \frac{3}{2}$$

$$\boxed{= \frac{5}{2}}$$

Q8)  $y = x^2(x+2) = x^3 + 2x^2$

a)  $\boxed{\frac{dy}{dx} = 3x^2 + 4x}$

b)  $y = x^2(x+2)$

When  $x=0$ ,  $y = 0^2(0+2) = \underline{0}$

When  $y=0$ ,  $x^2(x+2) = 0$

Either  $x=0$ ,  $x=0$ , or  $x=-2$

c) At  $x=0$ ,  $\frac{dy}{dx} = 3(0)^2 + 4(0) = \underline{0}$

At  $x=-2$ ,  $\frac{dy}{dx} = 3(-2)^2 + 4(-2)$   
 $= 3(4) - 8$   
 $= 12 - 8$   
 $= \underline{4}$

d)  $y = (x-k)^2(x-k+2)$ ,  $k > 2$

This is a horizontal translation (along the  $x$ -axis) of  $+k$ .

• When  $x=0$ ,  
 $y = (0-k)^2(0-k+2)$   
 $y = (-k)^2(2-k)$   
 $y = k^2(2-k)$

• When  $y=0$ ,  
 $(x-k)^2(x-k+2) = 0$   
 Either  $x=k$ ,  $x=k$ , or  $x=k-2$

Q9a) Scheme 1: First term,  $a = £P$   
Common difference,  $d = £(2T)$

$$S_n = \frac{n}{2} (2a + (n-1)d)$$

$$S_{10} = \frac{10}{2} (2P + (10-1)(2T))$$

$$S_{10} = 5(2P + 18T)$$

$$\boxed{S_{10} = £(10P + 90T)}$$

b) Scheme 2: First term,  $a = £(P + 1800)$   
Common difference,  $d = £T$

$$S_n = \frac{n}{2} (2a + (n-1)d)$$

$$S_{10} = \frac{10}{2} (2(P + 1800) + (10-1)T)$$

$$S_{10} = 5(2P + 3600 + 10T - T)$$

$$S_{10} = 5(2P + 3600 + 9T)$$

$$S_{10} = £(10P + 45T + 18000)$$

$$\text{But, } 10P + 45T + 18000 = 10P + 90T$$

$$18000 = 45T$$

$$\boxed{T = 400}$$

$$c) U_n = a + (n-1)d$$

$$\text{For scheme 2, } U_{10} = (P+1800) + (10-1)T$$

$$U_{10} = (P+1800) + 9(400)$$

$$29850 = P + 1800 + 3600$$

$$29850 = P + 5400$$

$$\boxed{P = 24450}$$

$$Q10a) y = 2 - \frac{1}{x}, x \neq 0$$

When the curve crosses the  $x$ -axis,  $y=0$

$$\text{So, } 0 = 2 - \frac{1}{x}$$

$$2 = \frac{1}{x}$$

$$2x = 1$$

$$x = \frac{1}{2}$$

$$\therefore \boxed{A \text{ is at } \left(\frac{1}{2}, 0\right)}$$

$$b) \quad y = 2 - \frac{1}{x}$$

$$y = 2 - x^{-1}$$

$$\frac{dy}{dx} = x^{-2}$$

$$= \frac{1}{x^2}$$

$$\text{When } x = \frac{1}{2}, \quad \frac{dy}{dx} = \frac{1}{(\frac{1}{2})^2} = \frac{1}{\frac{1}{4}} = 4$$

The gradient of the normal at A would be  $-\frac{1}{4}$

Equation of normal:  $y - y_1 = m(x - x_1)$

using  $A(\frac{1}{2}, 0)$  and  $m = -\frac{1}{4}$ :

$$y - 0 = -\frac{1}{4} (x - \frac{1}{2})$$

$$4(y - 0) = -1(x - \frac{1}{2})$$

$$4y = -x + \frac{1}{2}$$

$$4y + x - \frac{1}{2} = 0 \quad \Rightarrow \quad \boxed{2x + 8y - 1 = 0}$$

c) To find points of intersection, solve simultaneous equations:

$$y = 2 - \frac{1}{x} \quad (1)$$

$$2x + 8y - 1 = 0 \quad (2)$$

Substitute (1) into (2):

$$2x + 8\left(2 - \frac{1}{x}\right) - 1 = 0$$

$$2x + 16 - \frac{8}{x} - 1 = 0$$

$$2x + 15 - \frac{8}{x} = 0$$

$$\frac{2x^2 + 15x - 8}{x} = 0$$

$$2x^2 + 15x - 8 = 0$$

$$(2x - 1)(x + 8) = 0$$

$$\text{Either } x = \frac{1}{2} \text{ or } x = -8$$

---

We already know that  $(\frac{1}{2}, 0)$  is a point of intersection, so find  $y$  when  $x = -8$

Substitute into (1) for  $y$ :

$$y = 2 - \frac{1}{-8} = 2 + \frac{1}{8} = \frac{17}{8}$$

$$\therefore B \text{ is at } \left(-8, \frac{17}{8}\right)$$
