## Question:

A sequence $a_{1}, a_{2}, a_{3}, \ldots$ is defined by

$$
\begin{aligned}
& a_{1} \quad=k \\
& a_{n+1}=2 a_{n}-3, \quad n \geq 1
\end{aligned}
$$

(a) Show that $a_{5}=16 k-45$

Given that $a_{5}=19$, find the value of
(b) $k$

6
(c) $\sum a_{r}$

$$
r=1
$$

## Solution:

(a)

$$
\begin{array}{rlr}
a_{n+1} & & =2 a_{n}-3 \\
n=1: & a_{2} & =2 a_{1}-3 \\
& =2 k-3 \\
n=2: & a_{3} & =2 a_{2}-3 \\

\text { with } n=1,2,3 \text { and } 4 .
\end{array}
$$

(b)

```
\(a_{5}=19\),
so \(16 k-45=19\)
\(16 k=19+45\)
\(16 k=64\)
\(k=4\)
```

(c)

6

$$
\sum_{r=1} a_{r}=a_{1}+a_{2}+a_{3}+a_{4}+a_{5}+a_{6}
$$

This
is not an arithmetic series.
$a_{1}=k \quad=4$
$a_{2}=2 k-3=5$
$a_{3}=4 k-9$
$=7$
$a_{4}=8 k-21$
$=11$
$a_{5}=16 k-45$
$=19$
From the original formula,

$$
a_{6}=2 a_{5}-3
$$

$$
=(2 \times 19)-3

$$
=35

You
cannot use a standard formula,
so work out each separate term and then add them together to find the required sum.

## Question:

An arithmetic sequence has first term $a$ and common difference $d$.
(a) Prove that the sum of the first $n$ terms of the series is

$$
\frac{1}{2} n[2 a+(n-1) d]
$$

Sean repays a loan over a period of $n$ months. His monthly repayments form an arithmetic sequence.

He repays $£ 149$ in the first month, $£ 147$ in the second month, $£ 145$ in the third month, and so on. He makes his final repayment in the $n$th month, where $n>21$.
(b) Find the amount Sean repays in the 21st month.

Over the $n$ months, he repays a total of $£ 5000$.
(c) Form an equation in $n$, and show that your equation may be written as

$$
n^{2}-150 n+5000=0
$$

(d) Solve the equation in part (c).
(e) State, with a reason, which of the solutions to the equation in part (c) is not a sensible solution to the repayment problem.

## Solution:

## Question:

A sequence is given by

& a_{1} \quad=2 \\

where $k$ is a constant.
(a) Show that $a_{3}=6 k^{2}-20 k+16$

Given that $a_{3}=2$,
(b) find the possible values of $k$.

For the larger of the possible values of $k$, find the value of
(c) $a_{2}$
(d) $a_{5}$
(e) $a_{100}$

Solution:
(a)

$$
n=1: \quad a_{2}=a_{1}^{2}-k a_{1} \quad \text { Use the given formula }

$a_{3}=2$ :
$6 k^{2}-20 k+16=2$
$6 k^{2}-20 k+14=0$

Divide
by 2 to make solution easier

Try to
$3 k^{2}-10 k+7=0$
$\begin{aligned} & (3 k-7) \\ & (k-1)\end{aligned}=0$ with $n=1$ and 2 .
$k=$
$\frac{7}{3}$ or $k=1 \quad$ using the quadratic formula. than

$$

& =(4-2 k)^{2}-k(4-2 k) \\
& =16-16 k+4 k^{2}-4 k+2 k^{2} \\
& a_{3}=6 k^{2}-20 k+16
\end{aligned}
$$

(c)

The larger $k$ value is $\frac{7}{3}$

$$
\begin{aligned}
a_{2} & =4-2 k=4-\left(2 \times \frac{7}{3}\right) \\
& =4-\frac{14}{3}=-\frac{2}{3}
\end{aligned}
$$

(d)

$$
\begin{array}{ll}
\begin{aligned}
a_{n+1} & =a_{n}^{2}-\frac{7}{3} a_{n} \\
n=3: a_{4} & =a_{3}^{2}-\frac{7}{3} a_{3} \\
\text { But } a_{3} & =2 \text { is given, so } \\
& =2^{2}-\left(\frac{7}{3} \times 2\right) \\
a_{4} & =4-\frac{14}{3}=\frac{-2}{3} \\
n=4: \quad a_{5} & =a_{4}^{2}-\frac{7}{3} a_{4} \\
& =\left(\frac{-2}{3}\right)^{2}-\left(\frac{7}{3} \times \frac{-2}{3}\right) \\
& =\frac{4}{9}+\frac{14}{9}=\frac{18}{9} \\
& =2

a_{5} &

$$
\begin{array}{ll}
a_{2} & =\frac{-2}{3}, a_{3}=2 \\
a_{4} & =\frac{-2}{3}, a_{5}=2

$$

Use the formula with $k=\frac{7}{3}$, for $n=3$ and 4 .

For even values
of $n, a_{n}=\frac{-2}{3}$. $\frac{-2}{3}$ and 2.
