

CORE 1

Summary Notes

1 Linear Graphs and Equations

$$y = mx + c$$

gradient = $\frac{\text{increase in } y}{\text{increase in } x}$

Gradient Facts

- Lines that have the same gradient are PARALLEL
- If 2 lines are PERPENDICULAR then $m_1 \times m_2 = -1$ or $m_2 = -\frac{1}{m_1}$
 e.g. $2y = 4x - 8$
 $y = 2x - 4$ gradient = 2
 gradient of perpendicular line = $-\frac{1}{2}$

Finding the equation of a straight line

e.g. Find the equation of the line which passes through (2,3) and (4,8)

$$\text{GRADIENT} = \frac{y_1 - y_2}{x_1 - x_2} \quad \text{GRADIENT} = \frac{3 - 8}{2 - 4} = \frac{-5}{-2} = \frac{5}{2}$$

Method 1

$$y - y_1 = m(x - x_1)$$

Using the point (2,3) $y - 3 = \frac{5}{2}(x - 2)$

$$y = \frac{5}{2}x - 2$$

$$2y = 5x - 4$$

Method 2

$$y = mx + c$$

Using the point (2,3)

$$3 = \frac{5}{2} \times 2 + c$$

$$c = -2$$

$$y = \frac{5}{2}x - 2$$

$$2y = 5x - 4$$

Finding the Mid-Point

Given the points

$$(x_1, y_1) \text{ and } (x_2, y_2) \text{ the midpoint is } \left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2} \right)$$

Finding the point of Intersection

Treat the equations of the graphs as simultaneous equations and solve

Find the point of intersection of the graphs $y = 2x - 7$ and $5x + 3y = 45$

$$\begin{aligned} \text{Substituting } y = 2x - 7 \text{ gives} \quad & 5x + 3(2x - 7) = 45 \\ & 5x + 6x - 21 = 45 \\ & 11x = 66 \\ & x = 6 \quad y = 2 \times 6 - 7 \\ & \quad \quad y = 5 \end{aligned}$$

Point of intersection = (6, 5)

2 Surds

- A root such as $\sqrt{5}$ that cannot be written exactly as a fraction is IRRATIONAL
- An expression that involves irrational roots is in SURD FORM e.g. $3\sqrt{5}$

- $\sqrt{ab} = \sqrt{a} \times \sqrt{b}$

- $\sqrt{\frac{a}{b}} = \frac{\sqrt{a}}{\sqrt{b}}$

$$\begin{aligned} \text{e.g. } \quad & \sqrt{75} - \sqrt{12} \\ & = \sqrt{5 \times 5 \times 3} - \sqrt{2 \times 2 \times 3} \\ & = 5\sqrt{3} - 2\sqrt{3} \\ & = 3\sqrt{3} \end{aligned}$$

- RATIONALISING THE DENOMINATOR
 $3 + \sqrt{2}$ and $3 - \sqrt{2}$ is called a pair of CONJUGATES

The product of any pair of conjugates is always a rational number
 e.g. $(3 + \sqrt{2})(3 - \sqrt{2}) = 9 - 3\sqrt{2} + 3\sqrt{2} - 2$
 $= 7$

Rationalise the denominator of $\frac{2}{1 - \sqrt{5}}$

$$\begin{aligned} \frac{2}{1 - \sqrt{5}} \times \frac{1 + \sqrt{5}}{1 + \sqrt{5}} &= \frac{2 + 2\sqrt{5}}{1 - 5} \\ &= \frac{2 + 2\sqrt{5}}{-4} \\ &= \frac{-1 - \sqrt{5}}{2} \end{aligned}$$

3. Quadratic Graphs and Equations

Solution of quadratic equations

- Factorisation

$$x^2 - 3x - 4 = 0$$

$$(x + 1)(x - 4) = 0$$

$$x = -1 \text{ or } x = 4$$

- Completing the square

$$x^2 - 4x - 3 = 0$$

$$(x - 2)^2 - (2)^2 - 3 = 0$$

$$(x - 2)^2 - 7 = 0$$

$$(x - 2)^2 = 7$$

$$x - 2 = \pm\sqrt{7}$$

$$x = 2 + \sqrt{7} \text{ or } x = 2 - \sqrt{7}$$

- Using the formula to solve $ax^2 + bx + c = 0$

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

E.g Solve $x^2 - 4x - 3 = 0$

$$x = \frac{-(-4) \pm \sqrt{(-4)^2 - 4 \times 1 \times (-3)}}{2 \times 1}$$

$$= \frac{4 \pm \sqrt{28}}{2}$$

$$= 2 \pm \sqrt{7}$$

- The graph of $y = ax^2 + bx + c$ crosses the y axis at $y = c$
It crosses or touches the x-axis if the equation has real solutions

The DISCRIMINANT of $ax^2 + bx + c = 0$ is the expression $b^2 - 4ac$

If $b^2 - 4ac > 0$ there are 2 real distinct roots

If $b^2 - 4ac = 0$ there is one repeated root

If $b^2 - 4ac < 0$ there are no real roots

Graphs of Quadratic Functions

- The graph of any quadratic expression in x is called a PARABOLA
- The graph of $y - q = k(x - p)^2$ is a TRANSLATION of the graph $y = kx^2$

In VECTOR notation this translation can be described as $\begin{bmatrix} p \\ q \end{bmatrix}$

The equation can also be written as $y = k(x - p)^2 + q$

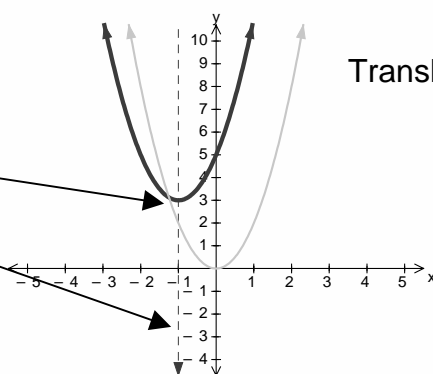

The VERTEX of the graph is (p,q)

The LINE OF SYMMETRY is $x = p$

$$2x^2 + 4x + 5 = 2(x + 1)^2 + 3$$

Vertex (-1,3)

Line of symmetry $x = -1$

Translation of $y = 2x^2$

$$\begin{bmatrix} -1 \\ 3 \end{bmatrix}$$

4 Simultaneous Equations

- Simultaneous equations can be solved by substitution to eliminate one of the variables

Solve the simultaneous equations $y = 2x - 7$ and $x^2 + xy + 2 = 0$

$$y = 7 + 2x$$

$$\text{so } x^2 + x(7 + 2x) + 2 = 0$$

$$3x^2 + 7x + 2 = 0$$

$$(3x + 1)(x + 2) = 0$$

$$x = -\frac{1}{3} \quad y = 6\frac{1}{3} \quad \text{or} \quad x = -2 \quad y = 3$$

- A pair of simultaneous equations can be represented as graphs and the solutions interpreted as points of intersection. If they lead to a quadratic equation then the **DISCRIMINANT** tells you the geometrical relationship between the graphs of the functions

$$b^2 - 4ac < 0 \quad \text{no points of intersection}$$

$$b^2 - 4ac = 0 \quad \text{1 point of intersection}$$

$$b^2 - 4ac > 0 \quad \text{2 points of intersection}$$

5 Inequalities

Linear Inequality

- Can be solved like a linear equation except **Multiplying or dividing by a negative value reverses the direction of the inequality sign**

e.g. Solve $-3x + 10 \leq 4$

$$-3x + 10 \leq 4$$

$$-3x \leq -6$$

$$x \geq 2$$

Quadratic Inequality

- Can be solved by either a graphical or algebraic approach.

e.g. solve the inequality $x^2 + 4x - 5 < 0$

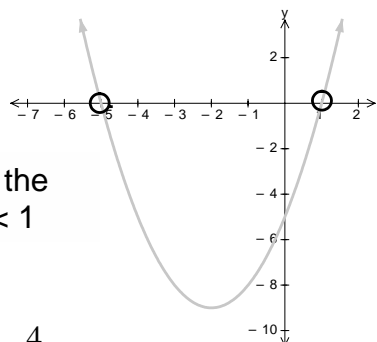

Algebraic $x^2 + 4x - 5 < 0$ factorising gives $(x + 5)(x - 1) < 0$

Using a sign diagram

$x + 5$	-	-	0	+	+	+	+	+	+
$x - 1$	-	-	-	-	-	0	+	+	+
$(x + 5)(x - 1)$	+	+	+	0	-	-	-	0	+

The product is negative for $-5 < x < 1$

Graphical

The curve lies below the x-axis for $-5 < x < 1$

6 Polynomials

Translation of graphs

To find the equation of a curve after a translation of $\begin{bmatrix} p \\ q \end{bmatrix}$ replace x with $(x-p)$ and replace y with $(y - q)$

e.g The graph of $y = x^3$ is translated by $\begin{bmatrix} 3 \\ -1 \end{bmatrix}$

The equation for the new graph is
 $y = (x - 3)^3 - 1$

Polynomial Functions

A polynomial is an expression which can be written in the form $a + bx + cx^2 + dx^3 + ex^4 + fx^5$ (a, b, c, \dots are constants)

- Polynomials can be divided to give a QUOTIENT and REMAINDER

$$\begin{array}{r}
 x^2 - 3x + 7 \\
 x + 2 \overline{) x^3 - x^2 + x + 15} \\
 \underline{x^3 + 2x^2} \\
 -3x^2 + x \\
 \underline{-3x^2 - 6x} \\
 7x + 15 \\
 \underline{7x + 14} \\
 1
 \end{array}$$

Quotient

Remainder

- REMAINDER THEOREM**
When $P(x)$ is divided by $(x - a)$ the remainder is $P(a)$
- FACTOR THEOREM**
If $P(a) = 0$ then $(x - a)$ is a factor of $P(x)$

e.g. The polynomial $f(x) = hx^3 - 10x^2 + kx + 26$ has a factor of $(x - 2)$
 When the polynomial is divided by $(x+1)$ the remainder is 15.
 Find the values of h and k .

Using the factor theorem $f(2) = 0$

$$8h - 40 + 2k + 26 = 0$$

$$8h + 2k = 14$$

Using the remainder theorem $f(-1) = 15$

$$-h - 10 - k + 26 = 15$$

$$h + k = 2$$

Solving simultaneously $k = 2 - h$

$$8h + 2(2 - h) = 14$$

$$6h + 4 = 14$$

Equation of a Circle

- A circle with centre (0,0) and radius r has the equation $x^2+y^2=r^2$
- A circle with centre (a,b) and radius r has the equation $(x - a)^2+(y - b)^2=r^2$
e.g. A circle has equation $x^2+ y^2 + 2x - 6y= 0$

Find the radius of the circle and the coordinates of its centre.

$$x^2 + 2x + y^2 - 6y = 0$$

$$(x + 1)^2 - 1 + (y - 3)^2 - 9 = 0$$

$$(x + 1)^2 + (y - 3)^2 = 10$$

$$\text{Centre (1, 3) radius} = \sqrt{10}$$

- A line from the centre of a circle to where a tangent touches the circle is perpendicular to the tangent. A **perpendicular** to a tangent is called a **NORMAL**.

e.g. C(-2,1) is the centre of a circle and S(-4,5) is a point on the circumference. Find the equations of the normal and the tangent to the circle at S.

$$\text{Gradient of SC is } \frac{1 - 5}{-2(-4)} = \frac{-4}{2} = -2$$

$$\text{Equation of SC } y = -2x + 7$$

$$\text{Gradient of the tangent} = -\frac{1}{-2} = \frac{1}{2}$$

$$\text{Equation of } y = \frac{1}{2}x + 7$$

- Solving simultaneously the equations of a line and a circle results in a quadratic equation.

$$b^2 - 4ac > 0 \quad \text{the line intersects the circle}$$

$$b^2 - 4ac = 0 \quad \text{the line is a tangent to the circle}$$

$$b^2 - 4ac < 0 \quad \text{the line fails to meet the circle}$$

8 Rates of Change

- The gradient of a curve is defined as the gradient of the tangent

Gradient is denoted $\frac{dy}{dx}$ if y is given as a function of x

Gradient is denoted by $f'(x)$ if the function is given as f(x)

- The process of finding $\frac{dy}{dx}$ or $f'(x)$ is known as DIFFERENTIATING

- Derivatives

$$f(x) = x^n \quad f'(x) = nx^{n-1}$$

$$f(x) = a \quad f'(x) = 0$$

$$y = x^3 + 4x^2 - 3x + 6$$

$$\frac{dy}{dx} = 3x^2 + 8x - 3$$

9 Using Differentiation

- If the value of $\frac{dy}{dx}$ is positive at $x = a$, then y is increasing at $x = a$
- If the value of $\frac{dy}{dx}$ is negative at $x = a$, then y is decreasing at $x = a$
- Points where $\frac{dy}{dx} = 0$ are called stationary points

Minimum and Maximum Points (Stationary Points)

Stationary points can be investigated

- by calculating the gradients close to the point (see above)
- by differentiating again to find $\frac{d^2y}{dx^2}$ or $f''(x)$
 - $\frac{d^2y}{dx^2} > 0$ then the point is a local minimum
 - $\frac{d^2y}{dx^2} < 0$ then the point is a local maximum

Optimisation Problems

Optimisation means getting the best result. It might mean maximising (e.g. profit) or minimising (e.g. costs)

10 Integration

- Integration is the reverse of differentiation

$$\int x^n dx = \frac{x^{n+1}}{n+1} + c \quad \leftarrow \text{Constant of integration}$$

e.g. Given that

$$f'(x) = 8x^3 - 6x \text{ and that } f(2) = 9 \text{ find } f(x)$$

$$\begin{aligned} f(x) &= \int 8x^3 - 6x dx \\ &= \frac{8x^4}{4} - \frac{6x^2}{2} + c \\ &= 2x^4 - 3x^2 + c \end{aligned}$$

To find c use $f(2) = 9$

$$32 - 12 + c = 9$$

$$c = -11$$

$$\text{So } f(x) = 2x^4 - 3x^2 - 11$$

11 Area Under a Graph

- The area under the graph of $y = f(x)$ between $x = a$ and $x = b$ is found by evaluating the definite integral

$$\int_a^b f(x) dx$$

e.g. Calculate the area under the graph of $y = 4x - x^3$ between the lines $x = 0$ and $x = 2$

$$\begin{aligned} \int_0^2 4x - x^3 dx &= \\ &= 2x^2 - \frac{x^4}{4} \\ &= (8 - 4) - (0 - 0) \\ &= 4 \end{aligned}$$

- An area BELOW the x -axis has a NEGATIVE VALUE
