

The Binomial Expansion Cheat Sheet

The binomial expansion can be used to expand brackets raised to large powers. It can be used to simplify probability models with a large number of trials, such as those used by manufacturers to predict faults.

Pascal's triangle

You can use Pascal's triangle to quickly expand expressions such as $(x + 2y)^3$. Consider the expansions of $(a + b)^n$ for $n = 0, 1, 2, 3$ and 4:

$$\begin{aligned}
 (a + b)^0 &= 1 \\
 (a + b)^1 &= 1a + 1b \\
 (a + b)^2 &= 1a^2 + 2ab + 1b^2 \\
 (a + b)^3 &= 1a^3 + 3a^2b + 3ab^2 + 1b^3 \\
 (a + b)^4 &= 1a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + 1b^4
 \end{aligned}$$

Each coefficient is the sum of the 2 coefficients immediately above it

Every term in the expansion of $(a + b)^n$ has total index n :
 In the $6a^2b^2$ term the total index is $2 + 2 = 4$.
 In the $4ab^3$ term the total index is $1 + 3 = 4$.

Pascal's triangle is formed by adding adjacent pairs of the numbers to find the numbers on the next row.

Here are the first 7 rows of Pascal's triangle:

$$\begin{array}{c}
 1 \\
 1 + 1 \\
 1 + 2 + 1 \\
 1 + 3 + 3 + 1 \\
 1 + 4 + 6 + 4 + 1 \\
 1 + 5 + 10 + 10 + 5 + 1 \\
 1 + 6 + 15 + 20 + 15 + 6 + 1
 \end{array}$$

The third row of Pascal's triangle gives the coefficients in the expansion of $(a + b)^2$

The $(n + 1)$ th row of Pascal's triangle gives the coefficients in the expansion of $(a + b)^n$.

Example 1:

Use Pascal's triangle to find the expansions of:

a. $(x + 2y)^3$ b. $(2x - 5)^4$

a. $(x + 2y)^3$
 The coefficients are 1, 3, 3, 1 so:

$$(x + 2y)^3 = 1x^3 + 3x^2(2y) + 3x(2y)^2 + 1(2y)^3 \\
 = x^3 + 6x^2y + 12xy^2 + 8y^3$$

Index = 3 so look at the 4th row of Pascal's triangle to find the coefficients.

This is the expansion of $(a + b)^3$ with $a = x$ and $b = 2y$. Use brackets to ensure you don't make a mistake.

b. $(2x - 5)^4$
 The coefficients are 1, 4, 6, 4, 1 so:

$$(2x - 5)^4 = 1(2x)^4 + 4(2x)^3(-5) + 6(2x)^2(-5)^2 + 4(2x)(-5)^3 + 1(-5)^4 \\
 = 16x^4 - 160x^3 + 600x^2 - 1000x + 625$$

Index = 4 so look at the 5th row of Pascal's triangle.

This is the expansion of $(a + b)^4$ with $a = 2x$ and $b = -5$

Example 2:

The coefficient of x^2 in the expansion of $(2 - cx)^3$ is 294. Find the possible values of the constant c . (Note: if there is an unknown in the expression, form an equation involving the unknown)

The coefficients are 1, 3, 3, 1:
 The term in x^2 is $3 \times 2(-cx)^2 = 6c^2x^2$
 So, $6c^2 = 294$
 $c^2 = 49 \Rightarrow c \pm 7$

Factorial notation

Combinations and factorial notation can help you expand binomial expressions. For larger indices, it is quicker than using Pascal's triangle.

Using factorial notation $3 \times 2 \times 1 = 3!$

You can use factorial notation and your calculator to find entries in Pascal's triangle quickly. The number of ways of choosing r items from a group of n items is written as ${}^n C_r$ or $\binom{n}{r}$:

$${}^n C_r = \binom{n}{r} = \frac{n!}{r!(n-r)!}$$

The r th entry in the n th row of Pascal's triangle is given by ${}^{n-1} C_{r-1} = \binom{n-1}{r-1}$

Example 3: Calculate

- a. $5!$ b. ${}^5 C_2$ c. the 6th entry in the 10th row of Pascal's triangle

a. $5! = 5 \times 4 \times 3 \times 2 \times 1 = 120$

b. ${}^5 C_2 = \frac{5!}{2!3!} = \frac{120}{12} = 10$

c. ${}^9 C_5 = 126$

Use the ${}^n C_r$ and ! functions on your calculator to answer this question.

You can calculate ${}^5 C_2$ by using the ${}^n C_r$ function on your calculator.

$${}^n C_r = \frac{n!}{r!(n-r)!} = \frac{5!}{2!(5-2)!}$$

The r th entry in the n th row is ${}^{n-1} C_{r-1}$

The binomial expansion

The binomial expansion is a rule that allows you to expand brackets. You can use $\binom{n}{r}$ to work out the coefficients in the binomial expansion. For example, in the expansion of $(a + b)^5 = (a + b)(a + b)(a + b)(a + b)(a + b)$, to find the b^3 term you can choose multiples of b from 3 different brackets. You can do this in $\binom{5}{3}$ ways so the b^3 term is $\binom{5}{3} a^2 b^3$.

The binomial expansion is:

$$(a + b)^n = a^n + \binom{n}{1} a^{n-1} b + \binom{n}{2} a^{n-2} b^2 + \dots + \binom{n}{r} a^{n-r} b^r + \dots + b^n$$

where $\binom{n}{r} = {}^n C_r = \frac{n!}{r!(n-r)!}$

Example 4: Use the binomial theorem to find the expansion of $(3 - 2x)^5$.

$$(3 + 2x)^5 = 3^5 + \binom{5}{1} 3^4(-2x) + \binom{5}{2} 3^3(-2x)^2 + \binom{5}{3} 3^2(-2x)^3 + \binom{5}{4} 3^1(-2x)^4 + (-2x)^5 \\
 = 243 - 810x + 1080x^2 - 720x^3 + 240x^4 - 32x^5$$

There will be 6 terms. Each term has a total index of 5. Use $(a + b)^n$ with $a = 3$, $b = -2x$ and $n = 5$

Solving Binomial Problems

You can use the general term of the binomial expansion to find individual coefficients in a binomial expansion.

In the expansion of $(a + b)^n$ the general term is given by $\binom{n}{r} a^{n-r} b^r$.

Example 6:

- a. Find the coefficient of x^4 in the binomial expansion of $(2 + 3x)^{10}$.

$$\begin{aligned}
 x^4 \text{ term} &= \binom{10}{4} 2^6 (3x)^4 \\
 &= 210 \times 64 \times 81x^4 \\
 &= 1088640x^4
 \end{aligned}$$

The coefficient of x^4 in the binomial expansion of $(2 + 3x)^{10}$ is 1088640.

- b. Find the coefficient of x^3 in the binomial expansion of $(2 + x)(3 - 2x)^7$.

$(3 - 2x)^7$ First, find the first four terms of the binomial expansion of $(3 - 2x)^7$

$$\begin{aligned}
 &= 3^7 + \binom{7}{1} 3^6(-2x) + \binom{7}{2} 3^5(-2x)^2 + \binom{7}{3} 3^4(-2x)^3 + \dots \\
 &= 2187 - 10206x + 20412x^2 - 22680x^3 + \dots \\
 &\Rightarrow (2 + x)(2187 - 10206x + 20412x^2 - 22680x^3 + \dots)
 \end{aligned}$$

Now expand the brackets $(2 + x)(3 - 2x)^7$

$$\begin{aligned}
 x^3 \text{ term} &= 2 \times (-22680x^3) + x \times 20412x^2 \\
 &= -24948x^3
 \end{aligned}$$

The coefficient of x^3 in the binomial expansion of $(2 + x)(3 - 2x)^7$ is -24948.

There are 2 ways of making the x^3 term: (constant term \times x^3 term) and (x term \times x^2 term)

Binomial Estimation

If the value of x is less than 1, then x^n gets smaller as n gets larger. If x is small you can sometimes ignore large powers of x to approximate a function or estimate a value.

Example 9:

- a. Find the first four terms of the binomial expansion, in ascending powers of x , of $(1 - \frac{x}{4})^{10}$.

$$\begin{aligned}
 (1 - \frac{x}{4})^{10} &= 1^{10} + \binom{10}{1} 1^9(-\frac{x}{4}) + \binom{10}{2} 1^8(-\frac{x}{4})^2 + \binom{10}{3} 1^7(-\frac{x}{4})^3 + \dots \\
 &= 1 - 2.5x + 2.8125x^2 - 1.875x^3 + \dots
 \end{aligned}$$

- b. Use your expansion to estimate the value of 0.975^{10} , giving your answer to 4 decimal places.

$$\begin{aligned}
 \text{We want } (1 - \frac{x}{4}) &= 0.975 \\
 \frac{x}{4} &= 0.025 \\
 x &= 0.1
 \end{aligned}$$

Calculate value of x

$$\begin{aligned}
 \text{Substitute } x = 0.1 \text{ into the expansion for } (1 - \frac{x}{4})^{10} \text{ from part a:} \\
 0.975^{10} &\approx 1 - 0.25 + 0.028125 - 0.001875 \\
 &= 0.77625
 \end{aligned}$$

$0.975^{10} \approx 0.7763$ to 4 d.p. Using a calculator, $0.975^{10} = 0.77632962$. so, approximation is correct.
