Determine the Specific Latent Heat of a Phase Change

Method 1: Determine the Specific Latent Heat of a Solid

- Set up apparatus as shown in diagram
- Weigh each of the **beakers** and record their **initial mass**
- Crush the **ice** and put it into the **funnel**, packed closely
- Fully submerge the **immersion heater** into the funnels of ice; one of the heaters are switched on while the other is not as a **control**, start the **stopwatch**
- Record the voltage and current across the heater
- After **5 minutes**, switch off the heater and record the final mass of water in each of the beakers
- Calculate the total mass of water melted in the given time of 5 minutes, by finding the difference between the initial and final mass in each of the beakers
- **Mass of ice melted by heater (Δm) = Total mass melted – Mass melted due to heat from surroundings**
 - Therefore, $\Delta m = \text{Mass melted in beaker} - \text{Mass melted in control}$
- Find the s:

$$L_f = \frac{VIt}{\Delta m}$$

Where $t = 300\text{s}$, L_f is specific latent heat of fusion, v is voltage and I is current.

Safety

- Melted ice may drip onto the floor creating a slipping hazard, ensure that there is a beaker to catch the melted ice

Evaluation

- Uncertainty is $\pm 1^\circ\text{C}$ (**uncertainty** in each temperature measurement is $\pm 0.5^\circ\text{C}$ but the measurements are both used to calculate the change in temperature)
- The ice must be melting so that it is at **0°C** , as the method does not account for heating the ice up to 0°C
- Ice must be **crushed** so that it cools the water down quickly, meaning less heat is absorbed from the room as the mixture is below room temperature - insulate the container
- If heat from the room enters, **L is too small** as temperature doesn't get as low as it should be

Method 2: Determine the Specific Latent Heat of a Liquid

- Set up the **double-walled glass vessel** and other apparatus, as shown above
- Measure initial mass, m_i , of the beaker
- Switch on **immersion heater** and start the **stopwatch**
- Record V , voltage, and I , current
- The **liquid** situated in the **inner section** of the tube will come to a boil and the vapour passes through the **small holes**, into the outer tube
- As the vapour passes through the **condenser** it becomes liquid again and collects in the **beaker**
- After 5 minutes, switch off heater, measure the final mass, m_f , of the beaker filled with water
- Find the mass of liquid which evaporates in 5 minutes, m_1 , as $m_1 = m_f - m_i$
- Repeat procedure at least 3 times and find mean m_1
- Find m_2 , the mass evaporated in a **different time interval** (e.g. 3 minutes), using the same procedure as above
- Considering the masses:
 - $m_1 =$ mass evaporated by heater in 5 minutes + mass evaporated due to heat from surroundings (Q)
 - $m_2 =$ mass evaporated by heater in 3 minutes + Q

Subtracting the two equations:

$$m_1 - m_2 = \text{mass evaporated in 2 mins}$$

$$L_v = \frac{VI \cdot (t_1 - t_2)}{m_1 - m_2}$$

Where L_v is the specific latent heat of vaporisation, t_1 is the time taken for m_1 and t_2 is the time taken for m_2 .

Safety

- Risk of scalding from the vapour

Evaluation

- A clean beaker should be placed under the tube when the liquid drips at a **constant rate**
- If a **joulemeter** is connected, the energy input can be found directly
