

Edexcel A Biology A-Level Core Practical 9

Investigate the antimicrobial properties of plants, including aseptic techniques for the safe handling of bacteria.

Aseptic technique is used to avoid contamination of the sample from outside substances such as microorganisms. This is important to get reliable and repeatable data.

Aseptic Technique

- Wipe down surfaces with antibacterial cleaner both before and after experiment.
- Use a **Bunsen burner** in the work space so that **convection currents** draw microbes away from the culture.
- Flame the wire hoop before using to transfer bacteria.
- Flame the neck of any bottles before use to prevent any bacteria entering the vessel (air moves out so unwanted organisms don't move in).
- Keep all vessels containing bacteria open for the minimum amount of time.
- Close windows and doors to limit air currents.

Equipment

- Agar plate seeded with bacteria
- Sample of garlic
- Sample of mint
- Mortar and pestle
- Methylated spirit
- Pipette
- Paper discs
- Petri dish
- Forceps
- Tape

Method

- 1. Carry out aseptic techniques detailed above.
- 2. **Crush 3g** of the garlic and mint (separately) with methylated spirit. Shake occasionally.
- 3. Use a **sterile pipette** to transfer plant extract to paper disc.
- 4. Leave paper discs to dry for 10 minutes.
- 5. Use sterile forceps to place the paper disc onto a petri dish.
- 6. Lightly tape a lid on, **invert** and **incubate** at 25°C for 24 hours. DO NOT tape around the entire dish as this **prevents oxygen entering** and so promotes the growth of more harmful **anaerobic** bacteria.

- 7. Sterilise equipment used to handle bacteria and disinfect work surfaces.
- 8. Measure the **diameter** of the **inhibition zone** (clear circle) for each plant. DO NOT remove lid from agar plate.
- 9. Work out the **area** of the inhibition zone using the formula:

$$A = \frac{\pi d}{4}$$

where d is the diameter.

NB: Bacteria sample is incubated at **25°C** as incubating at 37°C (human body temperature) could enable pathogens to grow that are **harmful to humans**.

| Hazard | Risk | Safety Precaution | In emergency | Risk Level |
|----------------------|-----------------------------|--|---|--|
| Disinfectant | Flammable | Keep away from naked flame | Put out fire; seek assistance | Low |
| Biohazard | Contamination; infection | Use disinfectant; wash hands with soap after dissection; do not incubate at human body temperature; do not open agar plate post incubation | Seek assistance | Low/medium (depends on likeliness of bacteria sample used to cause infection) |
| Naked flame | Fire hazard; burns | Keep away from flammable materials; tie up long hair, keep away from edge of desk | Put out fire; seek assistance;run burns under cold water immediately | Low |
| Methylated Spirit | Flammable and toxic | Keep away from naked flame. Do not ingest. Wear gloves and goggles. | Seek assistance | Medium |

Risk Assessment

Graph

- Plot a bar chart of the area of the inhibition zone against plant.
- Graph could include **range bars** to show the **uncertainty** from the ruler in measuring the diameter.

Conclusion

• If there is a larger inhibition zone around the plant, it has killed more bacteria. Therefore, the larger the inhibition zone, the better the antimicrobial properties of the plant.
