# <u>Topic 5 – Carbonyl Compounds</u> <u>Revision Notes</u>

# 1. Introduction

- Carbonyl compounds contain the group C=O
- The C=O bond is polar with the C being + and the O -. Nucleophiles are attracted to the + C

# 2. <u>Aldehydes and ketones</u>

- The functional group in aldehydes is –CHO on the end of a chain e.g. ethanal CH<sub>3</sub>CHO
- The functional group in ketones is C=O <u>not</u> at the end of a chain e.g. propanone CH<sub>3</sub>COCH<sub>3</sub>
- Position of C=O needs to specified if ketone has five or more Cs i.e. butanone but pentan-2-one and pentan-3-one
- The characteristic reaction of aldehydes and ketones is nucleophilic addition (nucleophiles attracted to δ+ C, addition due to double bond)

# a) Oxidation

- Aldehydes react with mild oxidising agents such as Tollens' reagent and Fehling's solution
- Ketones do not react with Tollen's and Fehling's because they are not easily oxidised.
- Tollen's reagent is ammoniacal silver nitrate. The compound to be tested is warmed with Tollen's reagent.
- With Tollens' aldehydes produce a silver mirror e.g.

$$\begin{array}{ll} \mathsf{CH}_3\mathsf{CHO} + [\mathsf{O}] \to & \mathsf{CH}_3\mathsf{COOH} \\ \mathsf{Ag}^+(\mathsf{aq}) + \mathsf{e}^- \to & \mathsf{Ag(s)} \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ \end{array}$$

- Fehling's contains a blue copper (II) complex. The compound to be tested is warmed with Fehling's solution
- With Fehling's aldehydes produce a brick-red precipitate of copper (I) oxide, Cu<sub>2</sub>O

# b) Reduction

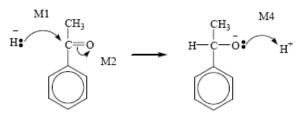

- Reduction, here, means addition of hydrogen
- A specific reducing agent for aldehydes and ketones is sodium borohydride, NaBH<sub>4</sub>. In equations the reducing agent is represented by [H]
- Aldehydes are reduced to primary alcohols by NaBH<sub>4</sub> e.g.

## $CH_3CHO + 2[H] \rightarrow CH_3CH_2OH$

• Ketones are reduced to secondary alcohols by NaBH<sub>4</sub> e.g.

## $C_6H_5COCH_3 + 2[H] \rightarrow C_6H_5CH(OH)CH_3$

• The mechanism for this reaction is called nucleophilic addition. The nucleophile is H<sup>-</sup> which is provided by NaBH<sub>4</sub>

• NaBH<sub>4</sub> will reduce C=O double bonds but it will not reduce C=C double bonds

e.g.  $CH_2 = CH-CHO + 2[H] \rightarrow CH_2 = CH-CH_2OH$ 

• To reduce both C=O and C=C use H<sub>2</sub> with Ni catalyst

e.g.  $CH_2 = CH - CHO + 2H_2 \rightarrow CH_3 CH_2 CH_2 OH$ 

## c) Addition of HCN

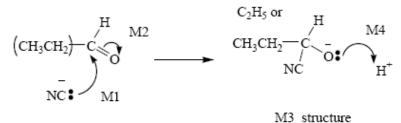

• Addition of HCN to an aldehyde or ketone produces a hydroxynitrile e.g.

### $CH_3CH_2CHO + HCN \rightarrow CH_3CH_2CH(OH)CN$ 2-hydroxybutanenitrile

2-nyuroxybutanenitine

### $CH_3COCH_3 + HCN \rightarrow CH_3C(OH)(CH_3)CN$ 2-hydroxy-2-methylpropanenitrile

- The aldehyde or ketone is refluxed with KCN(aq)
- HCN and KCN are toxic
- The mechanism for this reaction is nucleophilic addition. The nucleophile is CN<sup>-</sup>

#### ND structu

### 3. <u>Carboxylic acids</u>

- The functional group in carboxylic acids is –COOH on the end of a chain e.g. ethanoic acid CH<sub>3</sub>COOH
- They are weak acids (H<sup>+</sup> donors). The acidic H is in the –COOH group e.g.

$$CH_3COOH$$
  $CH_3COO^- + H^+$ 

• They react with carbonates and the fizzing produced can be used to distinguish carboxylic acids from other organic compounds

$$\begin{array}{l} 2CH_{3}COOH + CaCO_{3} \rightarrow (CH_{3}COO)_{2}Ca + H_{2}O + CO_{2} \\ \text{Ethanoic acid} \\ \text{calcium ethanoate} \end{array}$$

• Carboxylic acids react with alcohols to make and ester and water e.g.

 $CH_{3}COOH + CH_{3}OH \qquad CH_{3}COOCH_{3} + H_{2}O$ 

Ethanoic acid

methyl ethanoate

- This reaction is called esterification and requires a catalyst of concentrated H<sub>2</sub>SO<sub>4</sub>
- Note that C<sub>6</sub>H<sub>5</sub>COOH is called benzene carboxylic acid. Its salts are benzene carboxylates e.g. sodium benzene carboxylate

## 4. Esters

- Esters have the form RCOOR' where R and R' are alkyl groups such as CH<sub>3</sub>, C<sub>2</sub>H<sub>5</sub> etc
- Esters have pleasant smells and are used as flavourings in food and as solvents and plasticisers
- Esters can be hydrolysed by dilute acids and alkalis. This involves nucleophilic attack on the  $\delta$ + C of the carbonyl group by H<sub>2</sub>O or OH-

### a) Acid hydrolysis

• This is the reverse of esterification

### $CH_3COOC_2H_5 + H_2O$ $CH_3COOH + C_2H_5OH$

Ethyl ethanoate

- For acid hydrolysis, heat the ester with a dilute acid such as HCI
- Fats and oils are tri-esters. Acid hydrolysis of fats produces long-chain acids (fatty acids) and glycerol (propane-1,2,3,-triol)

### b) Alkaline hydrolysis

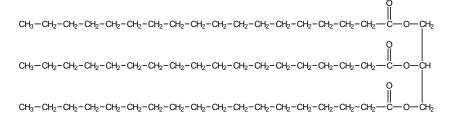

• This is similar to acid hydrolysis but produces the sodium salt of acid rather than acid itself. This is not reversible.

$CH_3COOC_2H_5 + NaOH \rightarrow$	CH₃COONa + C₂H₅OH
Ethyl ethanoate	sodium ethanoate

- For alkaline hydrolysis, heat the ester with dilute NaOH
- Alkaline hydrolysis of fats and oils produces glycerol and salts of fatty acids (soaps)

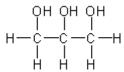

## 5. Fats and oils

• Animal fats and vegetable oils are tri-esters of glycerol and 3 fatty acids e.g.

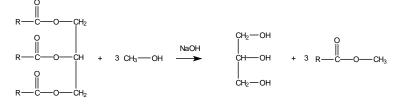

• Glycerol is propane-1,2,3-triol

- Acidic hydrolysis of animal fats and vegetable oils produces glycerol and long chain carboxylic acids (fatty acids)
- Alkaline hydrolysis of fats and oils produces glycerol and the sodium salts of fatty acids, which are used as soap

## 6. Biodiesel

- Biodiesel consists of the methyl esters of fatty acids
- Biodiesel can be made from cooking oil. The oil is mixed with methanol and potassium or sodium hydroxide is added as a catalyst

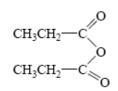

Source - http://www.chemsheets.co.uk/

• The use of biodiesel is increasing because of reduced greenhouse gas emissions, deforestation and pollution compared with petro-diesel (made from crude oil)

# 7. Acylation reactions

- The functional group in acyl chlorides is –COCI on the end of a chain e.g. ethanoyl chloride CH<sub>3</sub>COCI
- Acid anhydrides can be thought of as 2 molecules of acid that have lost a molecule of water e.g. propanoic anhydride, (CH<sub>3</sub>CH<sub>2</sub>CO)<sub>2</sub>O

Acyl chlorides react with water, alcohols, ammonia and primary amines in acylation reactions

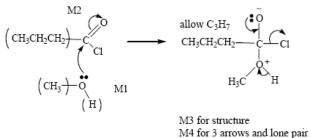

CH <sub>3</sub> COCI + H <sub>2</sub> O	$\rightarrow$	CH₃COOH + HCI
CH₃COCI + CH₃OH	$\rightarrow$	CH <sub>3</sub> COOCH <sub>3</sub> + HCI
CH <sub>3</sub> COCI + 2NH <sub>3</sub>	$\rightarrow$	CH₃CONH₂ + NH₄CI Ethanamide

#### $CH_{3}COCI + 2C_{6}H_{5}NH_{2} \rightarrow CH_{3}CONHC_{6}H_{5} + C_{6}H_{5}NH_{3}CI$ N-phenylethanamide

- These are vigorous reactions and white fumes are HCI are produced
- Water, alcohols, ammonia and primary amines are all nucleophiles. They have a lone pair on an O or N
- The reaction with an alcohol produces an ester. Compared with esterification (using a carboxylic acid), the acylation reaction has the benefits of not being reversible and not requiring a catalyst
- Acid anhydrides do the same reactions but the second product is ethanoic acid rather than HCI (so no white fumes are seen)

### $(CH_3CO)_2O + CH_3OH \rightarrow CH_3COOCH_3 + CH_3COOH$

- A similar reaction is used to manufacture aspirin. Ethanoic anhydride is used rather than ethanoyl chloride because the anhydride is cheaper, less corrosive and less susceptible to hydrolysis
- The mechanism for acylation is called nucleophilic addition-elimination

M4 for 3 arrows and lone pair (only allow for correct M3 or close)

M2 not allowed independent of M1,

but allow M1 for correct attack on C+ if M2 shown as independent first.
