Natural water

Water is first collected from **natural sources**, like **rivers and lakes**, and is then treated so it is safe for use. Water from these natural sources contains other substances that could be harmful to health, including:

- Microorganisms - natural water is the habitat for large numbers of bacteria and other microorganisms. Some of these are safe inside humans; however, many are **disease-causing** so the water must be treated, most commonly with **chlorine**, to kill these microorganisms.
- Ions - water dissolves ions from **rocks** and other material as it flows within rivers or to reach lakes/streams. Although a small amount of dissolved ions is important in water, **too much** is **dangerous** for your health.
- Dissolved gases - natural water contains dissolved **oxygen** and **carbon dioxide**, a byproduct of respiration from the microorganisms living in natural water; this is also required for photosynthesis in aquatic plants. Other gases from the **atmosphere** can dissolve into natural water.
- Pollutants - in the same way water dissolves ions as it runs over land on the way to the water source, it also dissolves many pollutants such as **pesticides, herbicides** and **chemical fertilisers**. In high concentrations, these can affect health.

Water is an essential resource

- Water covers about 2/3 of the Earth, but the majority cannot be drunk directly.
- Humans need drinking water with low levels of **dissolved salts** and **microbes** for **drinking** and **sanitation**.
- We also need water for **irrigating crops** and **agriculture**.
- The industry uses water as a **cooler** or **solvent**.

Potable water

- **Potable water** is water that is **safe to drink**.
- Potable water is not 'pure' because it contains dissolved substances, although to be safe it must have sufficiently **low levels of dissolved salts and microbes**.
- The methods used to produce potable water depend on available supplies of water and local conditions.

Sustainability

The demand for water has risen considerably across the world over the last 100 years, meaning there is a greater need than ever for a **sustainable water supply**. This includes:

Reducing water consumption

- Taking short **showers** instead of baths
- **Turn off taps** when they're not being used
- Installing a **short flush** button on toilets
- Using **leftover bath water** for things like watering plants
- Eat **less meat**
- Only boil the amount of water you **need**
- Put on **full** machine washing loads

- Use **dishwashers** instead of washing by hand

The methods of **abstraction** and **distribution** of water must also be evaluated to make them as **sustainable** as possible:

Abstracting water (the removal of water from water sources):

- **Desalination** of seawater
- Building **dams and reservoirs**
- Collecting from **surface sources** such as rivers, lakes and streams
- Collecting **rainwater**
- Accessing **underground sources**

Distributing water

Once the water has been collected and cleaned it has to be **distributed** to where it is needed. This is done via **underground piping systems** that take water directly to people's houses, business and farms etc.

Water treatment

The 3 main steps for **treatment** of water are **sedimentation**, **filtration** and **chlorination**. At the end of this process water is considered safe to use and can then be distributed.

1. Sedimentation:
 - Water is added to a large tank.
 - This stops it from flowing, allowing **large, insoluble particles** to **sink** to the bottom of the tank.
2. Filtration:
 - Water is flown through beds of sand and gravel of different sizes which removes **small insoluble particles**.
3. Chlorination:
 - **Chlorine gas** is bubbled through the water to **kill bacteria** and other **microorganisms**.

Fluoridation

Water fluoridation is a process where **fluoride** is added to water, different areas of the UK have **different amounts** of fluoride added to the water.

There is a **debate** on whether water should be fluoridated or not because there are both **disadvantages** and **advantages** to the process, as shown in the table:

Advantages	Disadvantages
<ul style="list-style-type: none"> • Strengthens the enamel of teeth which prevents tooth decay and cavities • Protects teeth from demineralisation 	<ul style="list-style-type: none"> • It is a form of mass medication as people have no say on how much fluoride is in their water • If children's teeth are exposed to too much fluoride they can develop

fluorosis

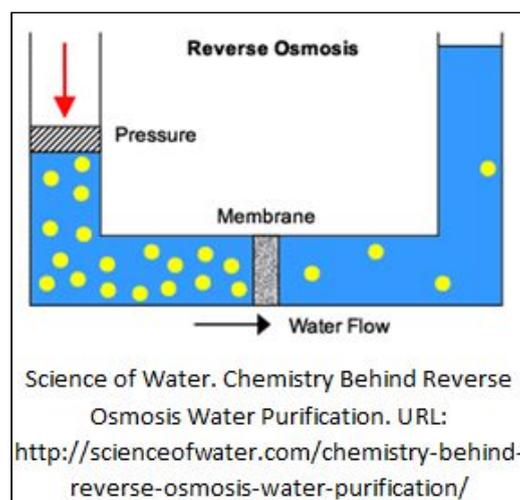

- People can make a choice themselves about fluoride by using toothpaste that contains it
- Links have been made between fluoride and thyroid problems, neurological disorders and some cancers - although there is no concrete evidence.

Methods of purification

Oceans contain **96.5% of the Earth's total water**, so taking seawater and making it safe to drink seems a good idea, especially in coastal places. Desalination is the removal of salt from seawater and can be done via 2 main methods - **distillation** and **reverse osmosis**.

Reverse Osmosis

Reverse osmosis uses a **selectively permeable membrane** that only allows water molecules to pass through and not other chemicals and ions. The seawater must be pushed through the membrane at **very high pressure**.

Distillation

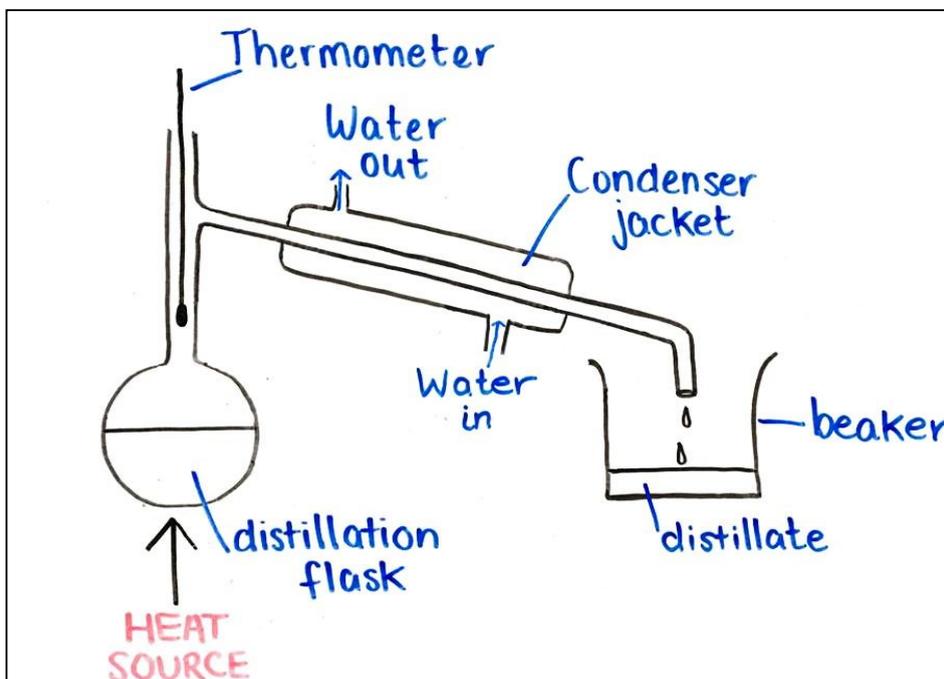

1. The seawater is **heated** causing pure water to **evaporate**.
2. The water vapour is collected and **cooled**, causing it to **condense** back into a liquid, giving **distilled water**.
3. The leftover salt may be used for various purposes.

Distillation is not only used to separate pure water from salt ions; it can also be used to separate **miscible liquids** by heating to certain temperatures to individually **evaporate and condense** different liquids.

For instance, the boiling point of ethanol is **78°C** and the boiling point of water is **100°C**, so by heating a mixture of ethanol and water to around **85°C** the ethanol would evaporate into a vapour which could be **condensed and collected** as a pure liquid while the water will remain as a liquid, thus **separating** the two liquids.

The apparatus used for distillation is:

The sustainability of desalination

Advantages	Disadvantages
<ul style="list-style-type: none"> • It is a useful water supply in countries with low rainfall and lots of coastline • The water produced from desalination is of a higher quality than the required standards of potable water • Using water from the ocean can help protect habitats for animals in natural sources such as rivers and lakes that can also be used to supply potable water 	<ul style="list-style-type: none"> • Desalination processes require a lot more energy than the typical water treatment process <ul style="list-style-type: none"> ◦ This makes it expensive and harder for poorer countries to afford ◦ This increases greenhouse gas emissions as a lot of fuel is required to heat the water in distillation and to create a high pressure in reverse osmosis. • Desalination plants are often far from where the water is needed, so lots of piping must be installed • Building of desalination plants is an expensive and high energy process

Solubility

What is solubility?

A substance (called the **solute**) is described as **soluble** if it will dissolve in another substance, known as the **solvent**. So when sugar dissolves in a cup of water, the solute is sugar and the solvent is water.

- Solubility depends on:
 - The identity of the **solute**
 - The identity of the **solvent**
 - The **temperature**
- Solubility is measured in terms of the **maximum mass of solute (in grams) that will dissolve in a given volume of solvent**.
 - For example, the solubility of sodium chloride, NaCl, is 36g/100g of water at 20°C
- A solvent is **saturated** when **no more solute will dissolve** in it

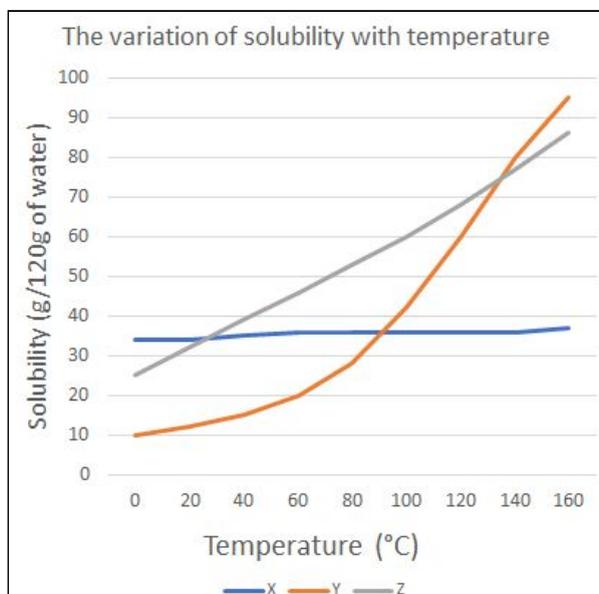

How to Measure Solubility

Method:

1. Gradually **add solute** to a **known volume of solvent** using a **spatula** and **stir** so it **dissolves**.
2. Add solute until **no more solute dissolves** - you will see the solute collecting at the bottom of the beaker.
3. Weigh a **weighing boat** and **record its mass**.
4. **Filter** the undissolved solute and discard it.
5. **Heat** the left over to solution to **evaporate the solvent**, leaving behind the solute that had dissolved. Add this to the weighing boat.
6. **Reweigh** the weighing boat and **calculate the mass of solvent that was dissolved**.

Solubility Curves

Solubility **varies with temperature** and a **solubility curve** shows this variation. Generally speaking, solubility **increases** as temperature increases. An example solubility curve is shown for 3 different solutes - X, Y and Z.

A solubility curve tells you many things:

- All 3 solute's solubility **increases with temperature**.
- The solubility of solute X **varies very little** with temperature.
- At lower temperatures solute X is most soluble whereas at higher temperatures solute Y is the most soluble.
- The solubilities of X and Z are the **same at around 25°C**

Hard water

Hard vs. soft water

	Hard water	Soft water
Composition	Contains dissolved magnesium ions and calcium ions. Water dissolves these ions as it runs over rocks such as limestone	Contains low concentrations of ions, magnesium and calcium ions in particular. It commonly contains sodium ions.
Action with soap	It is difficult to form a lather with hard water. Forms scum instead.	Readily forms a lather with soap

Temporary and permanent hardness

There are **2 types** of hard water - **temporary** and **permanent**

- **Temporary** hardness is caused by **dissolved calcium hydrogencarbonate - $\text{Ca}(\text{HCO}_3)_2$**
 - This hardness can be removed by **boiling** the water, when the following **thermal decomposition** reaction occurs:

$$\text{Ca}(\text{HCO}_3)_2(\text{aq}) \rightarrow \text{CaCO}_3(\text{s}) + \text{H}_2\text{O}(\text{l}) + \text{CO}_2(\text{g})$$
 - The **calcium carbonate, CaCO_3** , is a **solid** and is what forms on kettles when hard water is boiled. This decreases the efficiency of the heating element.
 - Calcium hydrogencarbonate forms in water when **rainwater** dissolves **carbon dioxide** from the atmosphere which reacts with **calcium carbonate** (found in limestone and other rocks), according to the following reaction:

$$\text{CaCO}_3(\text{s}) + \text{H}_2\text{O}(\text{l}) + \text{CO}_2(\text{g}) \rightarrow \text{Ca}(\text{HCO}_3)_2(\text{aq})$$
- **Permanent** hardness is caused by dissolved **calcium sulphate - CaSO_4**
 - This hardness **cannot** be removed by boiling the water.

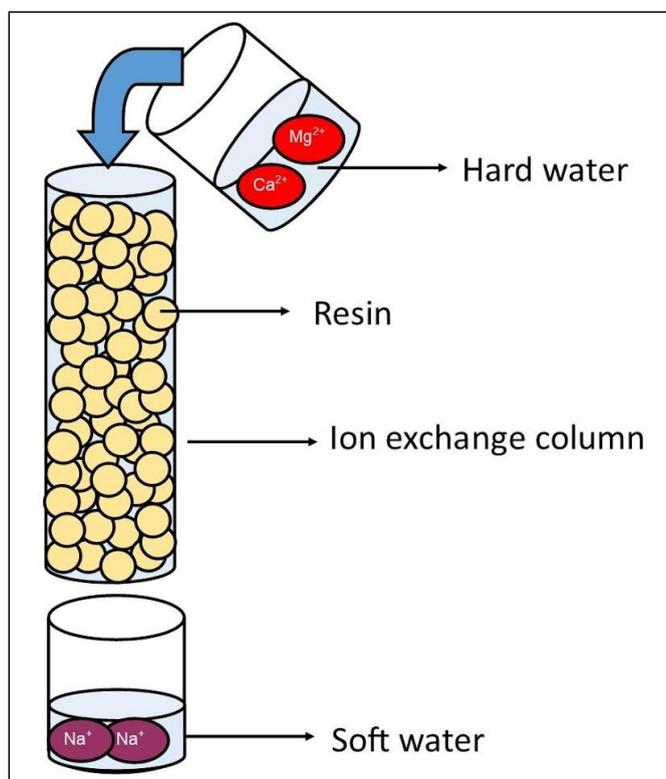

How to remove hardness

- Sodium carbonate - **Na_2CO_3** (washing soda) can remove **both** temporary and permanent hardness.

- **HIGHER TIER: Adds carbonate ions to the water which react with calcium ions to form solid calcium carbonate:**

$$\text{CO}_3^{2-} (\text{aq}) + \text{Ca}^{2+} (\text{aq}) \rightarrow \text{CaCO}_3 (\text{s})$$
- Ion exchange column - a column is packed with resin which contains sodium ions, as hard water flows through the column, Mg^{2+} and Ca^{2+} ions are exchanged for Na^+ ions, removing the magnesium and calcium ions.
 - **HIGHER TIER: As the water flows through the column Na^+ ions leave the resin and Mg^{2+} and Ca^{2+} ions instead get stuck to the resin. Overtime the column becomes saturated with calcium and magnesium ions and sodium chloride is run through the column to flush out the hard ions and replace them with Na^+ ions.**

- Distillation - the hard water is heated so the water evaporates and is then condensed and collected, leaving behind the ions that made it hard.

Water softening technique	Advantages	Disadvantages
Sodium carbonate	Cheap and easy Removes both temporary and permanent hardness	The calcium carbonate (limescale) builds up can block pipes
Ion exchange column	Removes both temporary and permanent hardness	The ion exchange column is expensive The column becomes saturated and less efficient

		over time
Distillation	Removes both temporary and permanent hardness	High energy process and therefore high cost

Advantages and disadvantages of hard water

While there are many methods for removing hardness from water, some people like to leave hardness in their water, as there are **many advantages** to it:

	Advantages	Disadvantages
Hard water	<ul style="list-style-type: none"> • The mineral ions in hard water help prevent some heart and cardiovascular diseases. Conversely the sodium ions in soft water can increase the risk of many of these diseases and cause high blood pressure • Many people prefer the taste of hard water • Calcium ions help strengthen teeth and bones 	<ul style="list-style-type: none"> • Limescale forms when hard water is used, reducing the efficiency of heating elements and potentially blocking water pipes • It is difficult to form a lather with soap but it is easy with soft water • Scum forms, wasting soap
