Topic 5: Perfect Competition, Imperfectly Competitive Markets and Monopoly

5.6 Monopoly and monopoly power

Notes

Characteristics of monopoly:

 Monopolies can be characterised by:

- Profit maximisation. A monopolist earns supernormal profits in both the short run and the long run.
- Sole seller in a market (a **pure monopoly**)
- High barriers to entry
- Price maker
- Price discrimination

 In the UK, when one firm dominates the market with more than 25% market share, the firm has **monopoly power**. For example, Google dominates the search engine market, with 90% share.

 Monopoly power can be gained when there are multiple suppliers. If two large firms in an oligopoly (several large sellers) have greater than 25% market share, they are said to have monopoly power. For example, Sainsbury's and Asda have more than 25% market share combined, so they are said to have monopoly power.

 There are very few examples of pure monopolies, but several firms have monopoly power. Firms operating in oligopolistic and monopolistic markets are price makers and they have varying degrees of monopoly power.

 Monopoly power is influenced by factors such as:

- **Barriers to entry:** The higher the barriers to entry, the easier it is for firms to maintain monopoly power. Examples of barriers to entry which can maintain monopoly power are:
 - **Economies of scale:** As firms grow larger, the average cost of production falls because of economies of scale. This means existing large firms have a cost advantage over new entrants to the market, which maintains their monopoly power. It deters new firms from entering the market, because they are not able to compete with existing firms.
 - **Limit pricing:** This involves the existing firm setting the price of their good below the production costs of new entrants, to make sure new firms cannot enter profitably.

- **Owning a resource:** Early entrants to a market can establish their monopoly power by gaining control of a resource. For example, BT owns the network of cables so new firms would find it very difficult to enter the market.
 - **Sunk costs:** If unrecoverable costs, such as advertising, are high in an industry, then new firms will be deterred from entering the market, because if they are unable to compete, they do not get the value of the costs back.
 - **Brand loyalty:** If consumers are very loyal to a brand, which can be increased with **advertising**, it is difficult for new firms to gain market share.
 - **Set-up costs:** If it is expensive to establish the firm, then new firms will be unlikely to enter the market.
- **The number of competitors:** The fewer the number of firms, the lower the barriers to entry, and the harder it is to gain a large market share.
 - **Advertising:** Advertising can increase consumer loyalty, making demand price inelastic, and creating a barrier to entry.
 - **The degree of product differentiation:** The more the product can be differentiated, through quality, pricing and branding, the easier it is to gain market share. This is because the more unique the product seems, the fewer competitors the firm faces.

Profit maximising equilibrium:

-  A monopolist earns supernormal profits in both the short run and the long run. This is at the point $MC = MR$, so the monopolist produces an output of Q_1 at a price of P_1 .
-  The shaded rectangle shows the area of supernormal profits.

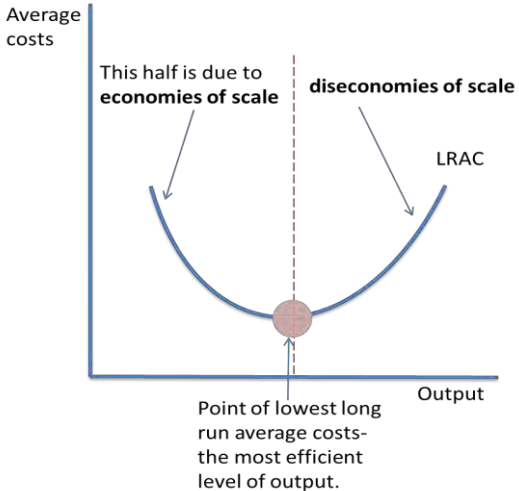

-  Since the firm is the sole supplier in the market, the firm's cost and revenue curve is the same as the industry's cost and revenue curve. Firms are price makers in a monopoly.
-  $P > MC$ in the diagram, due to profit maximisation which occurs at $MC = MR$, so there is allocative inefficiency in a monopoly.
-  $AR > AC$, so there are supernormal profits

 **Advantages and disadvantages of monopoly**

Disadvantages	Advantages
The basic model of monopoly suggests that higher prices and profits and inefficiency may result in a misallocation of resources compared to the outcome in a competitive market.	Monopolies can earn significant supernormal profits, so they might invest more in research and development. This can yield positive externalities, and make the monopoly more dynamically efficient in the long run. There could be more invention and innovation as a result. Moreover, firms are more likely to innovate if they can protect their ideas. This is more likely to happen in a market where there are high barriers to entry,

	such as in a monopoly.
Monopolies could exploit the consumer by charging them higher prices. This means the good is under-consumed, so consumer needs and wants are not fully met. This loss of allocative efficiency is a form of market failure.	If there is a natural monopoly, it might be more efficient for only one firm to provide the good or service, since having duplicates of the same infrastructure might be wasteful. For example, it might be considered inefficient and wasteful to have two lots of water suppliers.
Monopolies have no incentive to become more efficient, because they have few or no competitors, so production costs are high.	Monopolies could generate export revenue. For example, Microsoft generates a lot of export revenue for America.
<p>There is a loss of consumer surplus and a gain of producer surplus. If a monopolist raises the market price above the competitive equilibrium level, output will fall from Q_1 to Q_2. This leads to gains in producer surplus.</p>  <p>The graph shows a downward-sloping demand curve (D) and an upward-sloping supply curve (S). The equilibrium point is at price P_1 and quantity Q_1. A monopoly price is set at P_2, which is higher than P_1. This results in a lower quantity Q_2 being produced. The area between P_2 and P_1 up to Q_2 represents a loss of consumer surplus, while the area between P_2 and the supply curve up to Q_2 represents a gain in producer surplus.</p>	<p>Since monopolies are large, they can exploit economies of scale, so they have lower average costs of production. The long run average cost curve can be used to show this:</p>  <p>The graph shows a U-shaped long-run average cost (LRAC) curve. The vertical axis is labeled 'Average costs' and the horizontal axis is 'Output'. The minimum point of the curve is marked with a red dot and labeled 'Point of lowest long run average costs - the most efficient level of output.' The downward-sloping part of the curve is labeled 'This half is due to economies of scale' and the upward-sloping part is labeled 'diseconomies of scale'.</p>
Consumers do not get as much choice in a monopoly as they do in a competitive market.	High profits could be a source of government revenue through taxation.
